

# Earth as a System

A SYSTEM WITH 4 PRIMARY PARTS

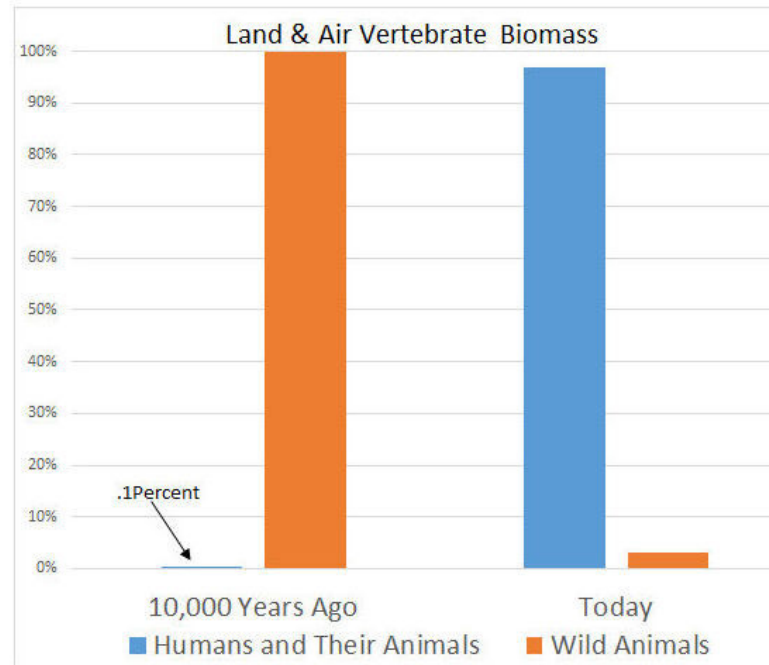

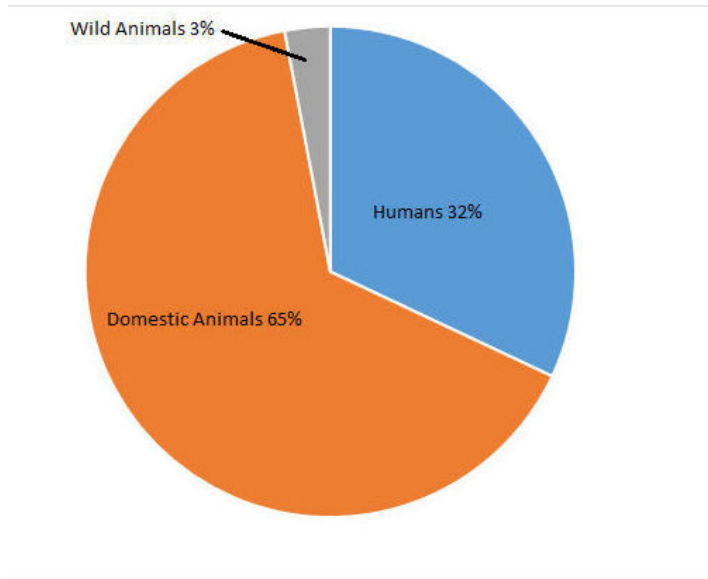

WATER (hydrosphere)

LAND (geosphere)

AIR (atmosphere)

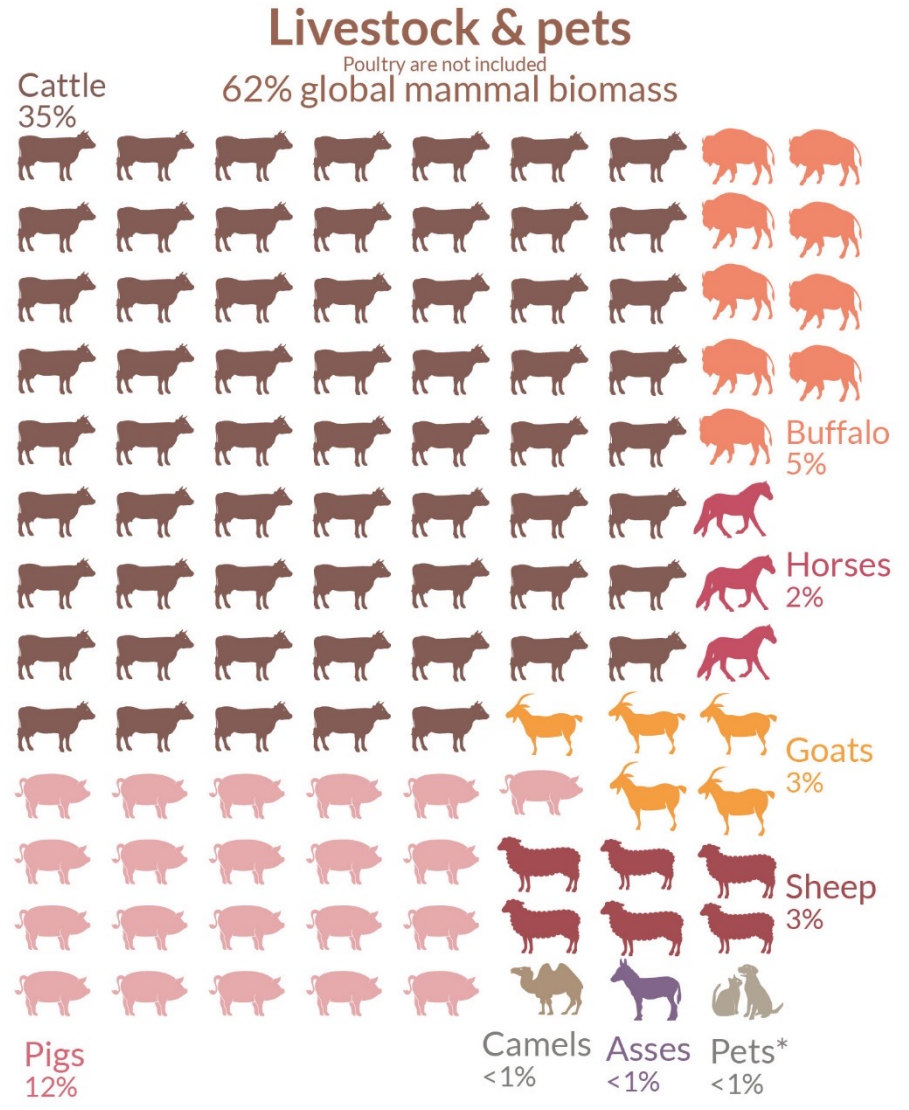

LIFE (biosphere)

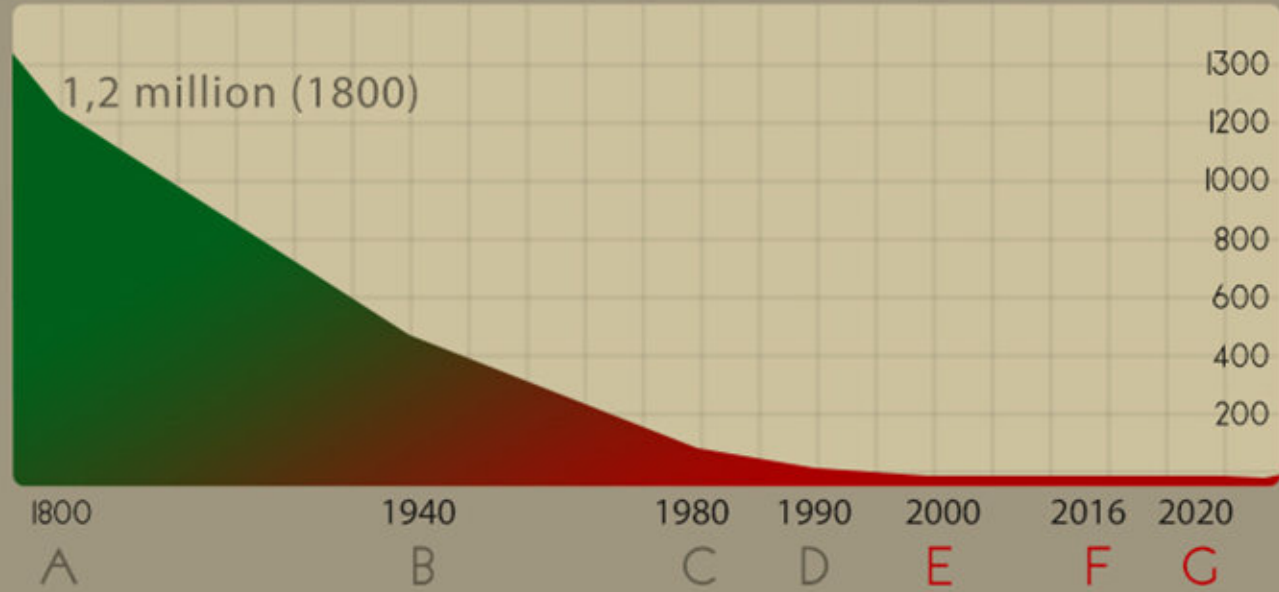

# Distribution of mammals on Earth

Mammal biomass is shown for the year 2015.  or  or  = 1 million tonnes carbon (C)

\*Bar-On et al. (2018) provide estimates of livestock only, without estimates of mammalian pets (e.g. cats and dogs).  
 Pets have been added as an additional category based on calculations from estimates of the number of pets globally and average biomass.  
 Data source: Bar-On et al. (2018). The biomass distribution on Earth. Images sourced from the Noun Project.

**E. Young**

E. Young is a small town country author of horror and sci-fi works. Strives to cultivate a general sense unease and wholesome pop culture references. Owns a multitude of cats and probably wants to talk to you about a movie or music from a band you've never heard of. Can also be found at *Bright Nightmares* or on the Twitter machine @xenoxands.

# Threats to biodiversity

## Changes in land and sea use, including habitat loss and degradation

This refers to the modification of the environment where a species lives, by complete removal, fragmentation or reduction in quality of key habitat. Common changes in use are caused by unsustainable agriculture, logging, transportation, residential or commercial development, energy production and mining. For freshwater habitats, fragmentation of rivers and streams and abstraction of water are common threats.

## Species overexploitation

There are both direct and indirect forms of overexploitation. Direct overexploitation refers to unsustainable hunting and poaching or harvesting, whether for subsistence or for trade. Indirect overexploitation occurs when non-target species are killed unintentionally, for example as bycatch in fisheries.

## Invasive species and disease

Invasive species can compete with native species for space, food and other resources, can turn out to be a predator for native species, or spread diseases that were not previously present in the environment. Humans also transport new diseases from one area of the globe to another.

## Pollution

Pollution can directly affect a species by making the environment unsuitable for its survival (this is what happens, for example, in the case of an oil spill). It can also affect a species indirectly, by affecting food availability or reproductive performance, thus reducing population numbers over time.

## Climate change

As temperatures change, some species will need to adapt by shifting their range to track a suitable climate. The effects of climate change on species are often indirect. Changes in temperature can confound the signals that trigger seasonal events such as migration and reproduction, causing these events to happen at the wrong time (for example misaligning reproduction and the period of greater food availability in a specific habitat).

**Figure 4: Different threat types in the Living Planet Database**

Descriptions of the major threat categories used in the Living Planet Database. This classification reflects the direct drivers with the largest global impact as identified by IPBES<sup>9</sup>; it is also followed by the IUCN Red List and is based on the original classification by Salafsky, N. et al. (2010)<sup>10</sup>. Source WWF/ZSL (2020)<sup>107</sup>.

**Figure 5: The proportion of threats recorded in each category for populations in each IPBES region<sup>9</sup>**

The number of populations with threat data available is shown next to the pie chart<sup>107</sup>. The colour of each section refers to the colour for each threat category on the opposite page.

**Figure 12: Humanity's Ecological Footprint against Earth's biocapacity in global hectares, 1961-2020**

Global overshoot, starting in the early 1970s, has increased since. The COVID-19 related footprint contraction - in lighter colours from 2016 onwards - is an estimate<sup>30, 31</sup>.

Key

- Carbon footprint<sup>34</sup> for absorbing emissions from fossil fuel burning and cement production
- Built-up land footprint for accommodating roads and buildings
- Fishing grounds footprint for wild and farmed seafood from oceans and freshwater
- Forest product footprint for fuel wood, pulp and timber
- Grazing land footprint for meat, dairy, leather and wool
- Cropland footprint for food, fibre, oil and feed crops, including rubber
- - - World biocapacity

**Humanity's Ecological Footprint by activities**

- Food
- Housing
- Personal transportation
- Goods
- Services

**Humanity's Ecological Footprint by land use**

Key

- Cropland footprint
- Grazing land footprint
- Forest product footprint
- Fishing grounds footprint
- Built-up land footprint
- Carbon footprint

**Figure 13: Humanity's Ecological Footprint by land use and by activities**

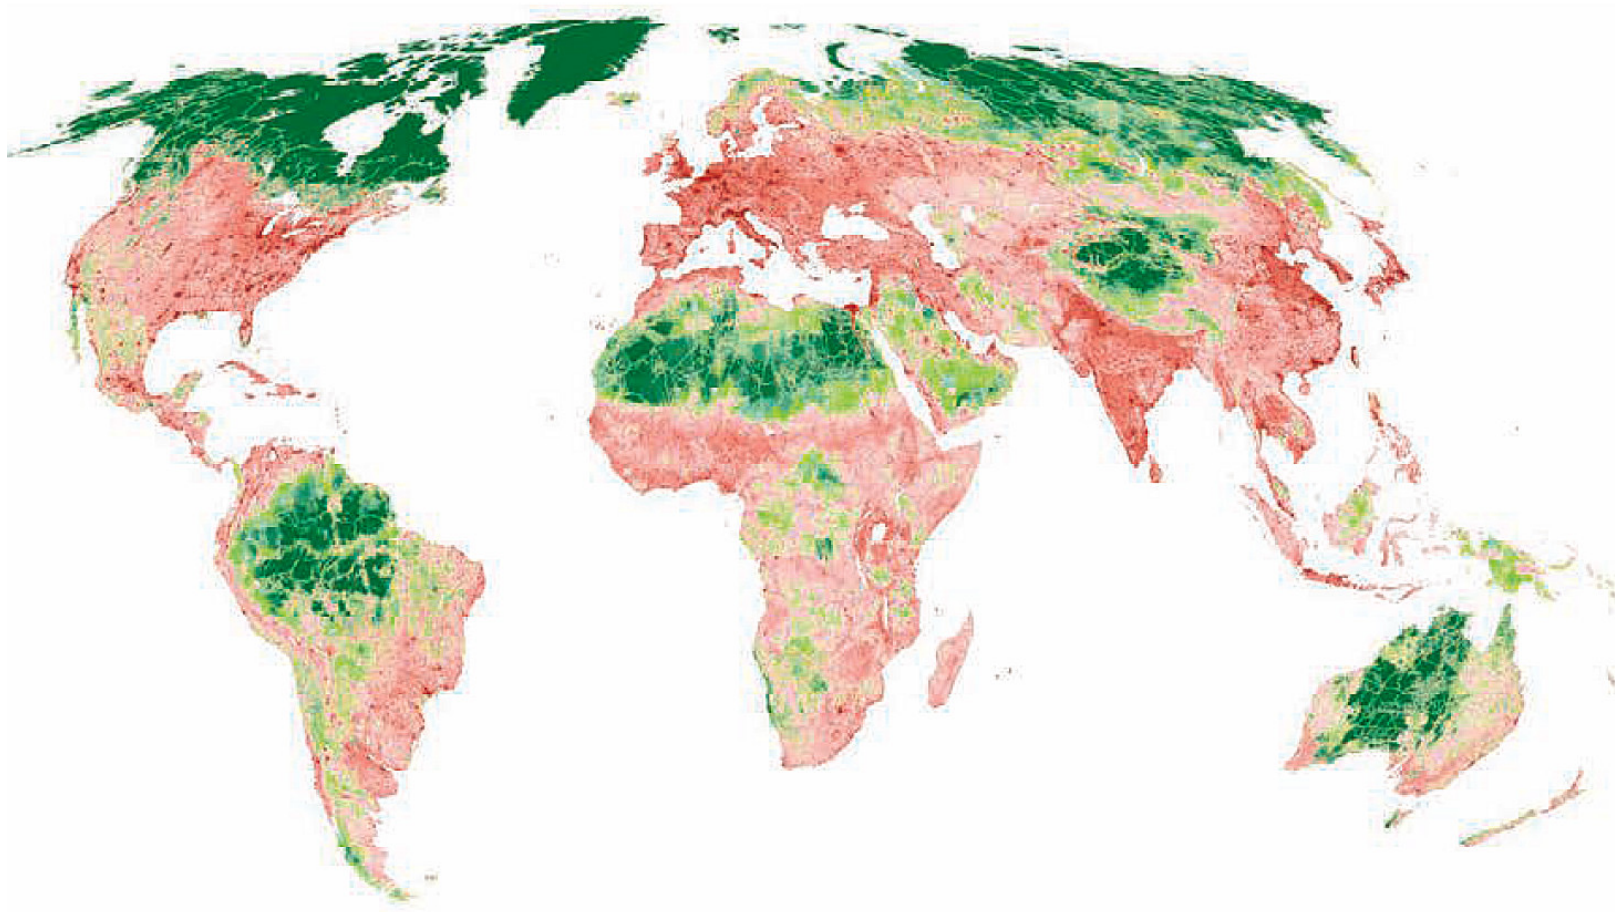

The Ecological Footprint measures how much demand human consumption places on the biosphere and compares it to what ecosystems can renew. In 2020, the world average Footprint amounts to 2.5 global hectares per person, compared to 1.6 global hectares of biocapacity. It can be broken down by area categories (outer circle) or, using Multi-Regional Input-Output Assessments, by activity fields (inner circle)<sup>35, 30, 29, 36</sup>.

*Key*

Damaged	Intact	Wilderness
 High: 50	 High: 1	 High: 0
 Low: 4	 Low: 4	 Low: 1

**Figure 19:**

*The proportion of each terrestrial biome (excluding Antarctica) considered wilderness (dark green, human footprint value of <1), intact (light green, human footprint value of <4), or highly modified by humanity (red, human footprint value of > or equal to 4)<sup>74</sup>.*

**Figure 17: Global land use in circa 2015**

The bar chart depicts shares of different uses of the global ice-free land area for approximately the year 2015. Bars are ordered along a gradient of decreasing land-use intensity from left to right. Each bar represents a broad land cover category; the numbers on top are the total percentage of the ice-free area covered, with uncertainty ranges in brackets. Intensive pasture is defined as having a livestock density greater than 100 animals/km<sup>2</sup>. The area of 'forest managed for timber and other uses' was calculated as total forest area minus 'primary/intact' forest area... Adapted from the IPCC Land Special Report on Land – Summary for Policy Makers (2019)<sup>73</sup>

Agriculture is responsible for 80% of global deforestation

Food systems release 29% of global GHGs

*Figure 15: The environmental impacts of food production*  
Sources: Adapted from CBD (2014)<sup>98</sup>, GSDR (2019)<sup>99</sup> and ELD Initiative (2015)<sup>103</sup>.

Agriculture accounts for 70% of freshwater use

Drivers linked to food production cause 70% of terrestrial biodiversity loss

Drivers linked to food production cause 50% of freshwater biodiversity loss

52% of agricultural production land is degraded

# Consumption around the world

Both human demand and natural resources are unevenly distributed across the Earth. The pattern of human consumption of these resources differs from resource availability, since resources

are not consumed at the point of extraction. The Ecological Footprint per person, across countries, provides insights into countries' resource performance, risks and opportunities<sup>37, 38, 29</sup>.

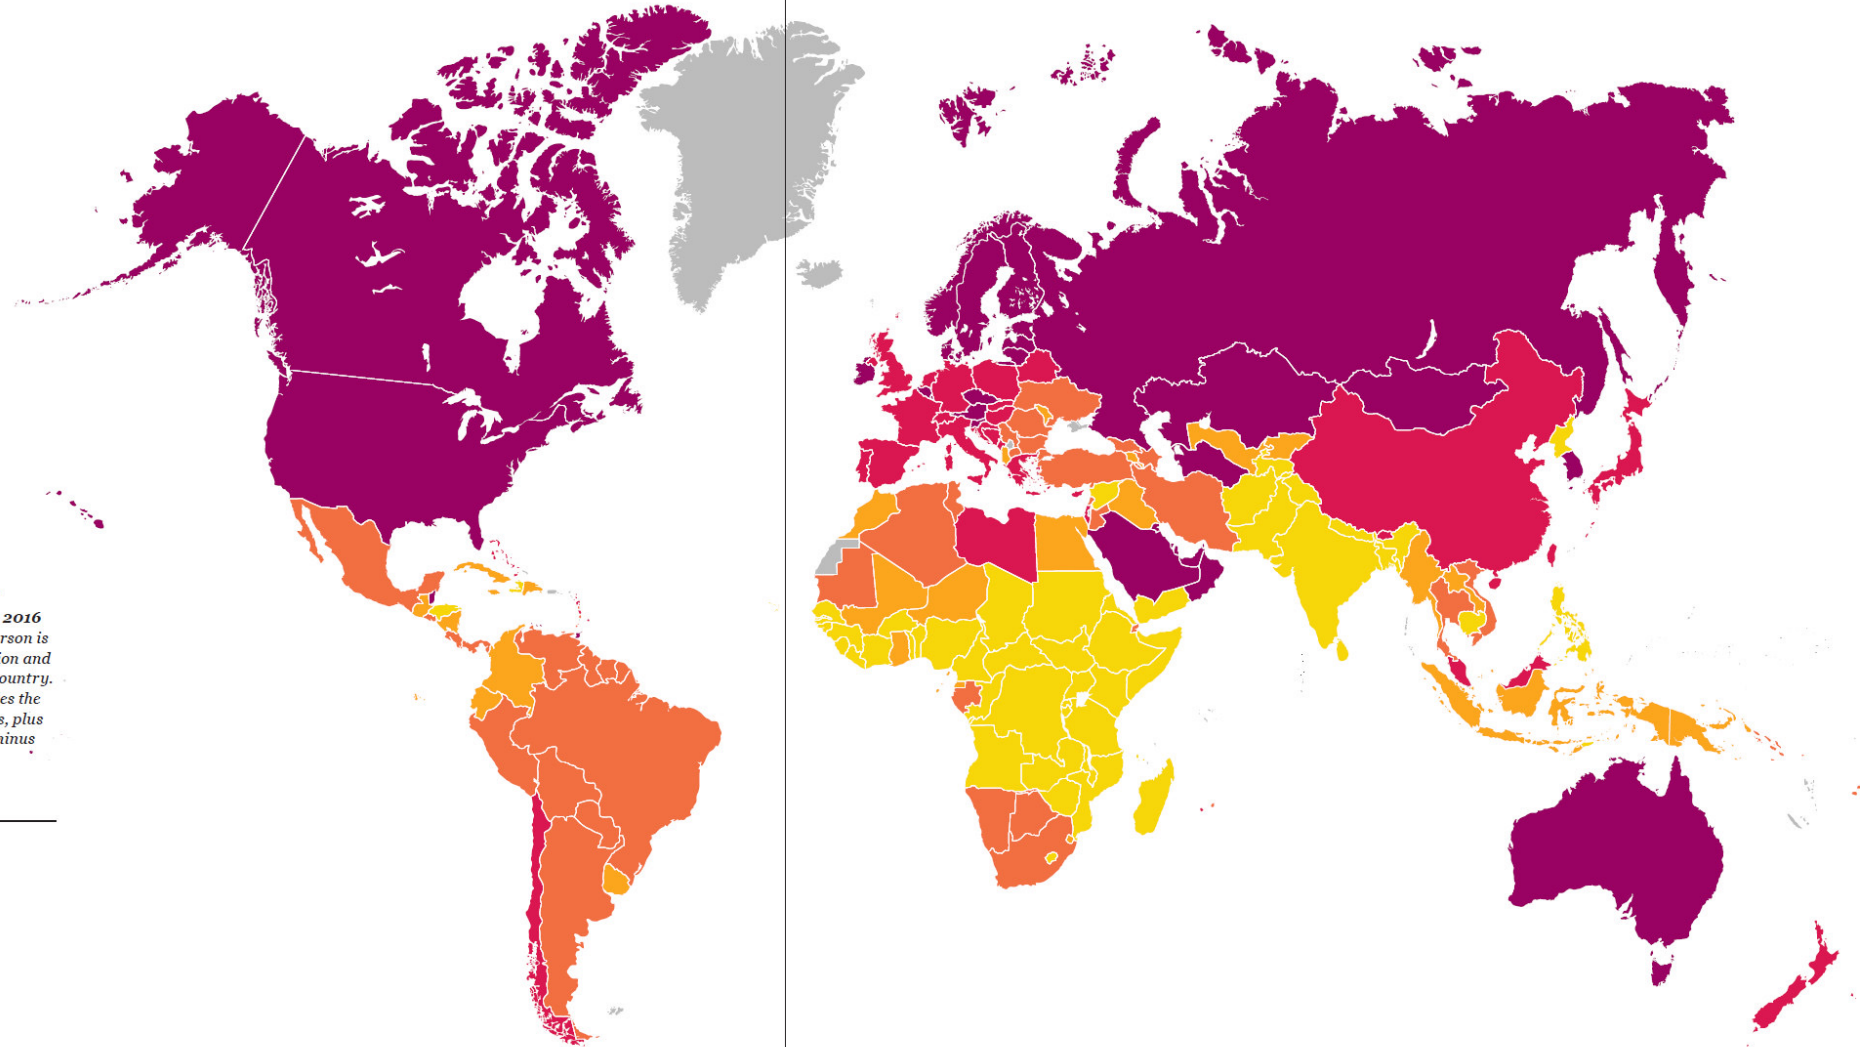

Varying levels of Ecological Footprint are due to different lifestyles and consumption patterns, including the quantity of food, goods and services residents consume, the natural resources they

use, and the carbon dioxide emitted to provide these goods and services.

**Figure 14: Global map of the Ecological Footprint of consumption per person in 2016**  
The Ecological Footprint per person is a function of both total population and rates of consumption within a country. A country's consumption includes the Ecological Footprint it produces, plus imports from other countries, minus exports<sup>39</sup>.

**Key**

- > 5 gha/person
- 3.5 - 5 gha/person
- 2 - 3.5 gha/person
- 1.6 - 2 gha/person
- < 1.6 gha/person
- Insufficient data
